Analgesia Guidance for Rodent Procedures

Important tips:
1. Expected post-procedural pain level is based on the procedure being performed optimally by skilled personnel. Sub-optimal performance of any procedure is likely to produce more pain than is typical.
2. Consider the effects of using the specific analgesic (NSAID or opioid) on the scientific objectives of the study.
3. Include multiple (or all) options in your protocol to maintain flexibility. See additional information on drugs below chart.
4. Animals should be monitored as follows: moderate pain → at least once daily; severe pain → at least twice daily until analgesia is done and the animal is stable (see green post-op card instructions).
5. Analgesia lasting longer than required is permitted (e.g. sustained release formulas).
6. More frequent dosing may be required in the initial post-op period, with less frequent dosing needed as the animal heals.
7. Other analgesic regimens may be proposed. Contact a veterinarian to discuss available alternatives. All analgesic regimens must be reviewed and approved by the IACUC prior to use.
8. Multi-modal pain relief (e.g. a combination of local anesthetic, opioid, and NSAID) is generally superior to single-modality analgesia.

</table>
| • Skin incision only (any site)                                                           | Mild Pain (analgesia to last at least 8 hours)                                                       | • Option 1: Local anesthetic (incisional)  
• Option 2: 1 dose of buprenorphine  
• Option 3: NSAID (to last at least 8 hours)                                                   |
| • Subcutaneous implant (e.g., osmotic pump, pellet, transponder)                          |                                                                                                     | General anesthesia is required.                                                                                 |
| • Catheter placement via cut down                                                        |                                                                                                     |                                                                                                                 |
| • Punch biopsy of skin                                                                     |                                                                                                     |                                                                                                                 |
| • Vascular access port implantation                                                       |                                                                                                     |                                                                                                                 |
| • Ocular (eye) procedure—minor                                                            |                                                                                                     |                                                                                                                 |
| • Embryo transfer via lumbar incision                                                    | Moderate Pain (analgesia needs to last 12-24 hours)                                                  | • Option 1: Lidocaine or Bupivacaine local at the time of surgery followed by NSAID (12-24 coverage)          |
| • Castration/ Vasectomy                                                                   |                                                                                                     | • Option 2: Buprenorphine + injectable NSAID (12-24 hour coverage)                                            |
| • Intracranial surgery—minor                                                             |                                                                                                     | • Option 3: Buprenorphine + oral NSAID (12-24 hour coverage)                                                 |
| • Thyroidectomy                                                                           |                                                                                                     | • Option 4: 1 dose of Buprenorphine-SR (lasts 72 hours)                                                      |
| • Thymectomy                                                                             |                                                                                                     | General anesthesia is required.                                                                                 |
| • Mammary fat pad manipulation                                                            |                                                                                                     |                                                                                                                 |
| • Orthopedic procedures—minor                                                            |                                                                                                     |                                                                                                                 |
| • Ocular (eye) procedure—moderate                                                         |                                                                                                     |                                                                                                                 |
| • Tissue dissection/transection (e.g. incisional biopsy or tumor removal)                  |                                                                                                     |                                                                                                                 |
| • Thoracotomy (use of local anesthetic on incision site is highly desirable— see following pages) | Severe Pain (analgesia needs to last 24-48 hours)                                                    | • Option 1: Lidocaine or Bupivacaine local at the time of surgery followed by buprenorphine +/- NSAID (thoracotomy) |
| • Laparotomy (for C-section, GI, kidney, spleen, liver, reproductive, or other abdominal procedures) |                                                                                                     | • Option 2: Buprenorphine + injectable NSAID (24-48 hour coverage)                                           |
| • Craniotomy—with bone removal— major                                                     |                                                                                                     | • Option 3: Buprenorphine-SR given 1 hour prior to surgery; +/- local anesthetic; +/- oral NSAID to reduce swelling and increase comfort |
| • Laminectomy/Vertebral surgery                                                           |                                                                                                     | General anesthesia is required.                                                                                 |
| • Nerve surgery                                                                           |                                                                                                     |                                                                                                                 |
| • Ocular (eye) procedure—major                                                            |                                                                                                     |                                                                                                                 |
| • Orthopedic procedure—major                                                              |                                                                                                     |                                                                                                                 |

### Major vs. Minor Procedures

- **Minor** procedures typically do not result in permanent or chronic impairment. Healing is rapid with little obvious change in the area or organ.

- **Major** procedures require more extensive tissue resection and organ involvement resulting in delayed healing or chronic inflammation.
Additional Information on Rodent Analgesics

I. Systemic analgesics

A. Buprenorphine (Buprenex®)
Narcotic/Opioid (Schedule III)
Drug concentration in ampule: 0.3 mg/ml
Analgesic duration: 4-8 hours
Dosages:
   Rats*: 0.01 – 0.05 mg/kg given SC (preferred route) or IP every 6-8 hours
   Mice: 0.05-0.1 mg/kg given SC (preferred route) or IP every 4-6 hours
   *may cause pica (eating of non-food substances) in rats; use lower dose range for Sprague-Dawley rats

B. Buprenorphine-Sustained Release (“Bup-SR”)
Narcotic/Opioid (Schedule III) from Zoopharm
Drug Concentration: 1 mg/ml (5 ml vial)
Analgesic duration: 72 hours

Bup-SR is preferred to standard Buprenorphine as it provides 72 hours of analgesic coverage with one single injection.

Dosages:
   Rats: 1.0 - 1.2 mg/kg* [for a single 72-hour SC injection]
   Mice: 0.5 – 1.0 mg/kg* [for a single 72-hour SC injection]

C. Carprofen (Rimadyl®) Non-steroidal anti-inflammatory (NSAID)

1. Carprofen Oral (chewable tabs): from Bio-serv
   Flavored chewable tablet containing 2 mg carprofen/5 gram tablet.
   How to use: Placebo tab (no carprofen) can be used 3 days prior to surgery to acclimate the animal. Place on the cage floor for easy access. The tablet is nutritionally complete, stimulates appetite, and allows animals time to recover undisturbed. It is important to verify that animals are eating the tablet in order to ensure appropriate analgesic coverage.
   Dosages:
      Rats: One 5 gm tablet per rat per day
      Mice: ¼ tablet per mouse per day (one 5 gm tablet for up to 4 mice)
2. Carprofen Oral (Drinking water):
   Drinking water is treated with injectable carprofen (50mg/ml) to provide therapeutic levels.  
   How to use: Determine size of water bottle used in cages (most commonly 400 ml bottles).  
   All water bottle doses are approximations based on normal daily water consumption for a 
   given species.  In order to provide adequate analgesia, carprofen-containing water bottles 
   must be placed on the cage at least 12 hours prior to painful procedures.  Change 
   carprofen-containing water bottles every 7 days.
   Dosages:
   Rats: 0.05mg to 0.1mg carprofen per ml water [Add 0.1 to 0.2 ml carprofen (50mg/ml) per 100 ml water]
   Mice 0.05mg carprofen per ml water [Add 0.1 ml carprofen (50 mg/ml) per 100 ml water]

3. Carprofen Injectable:
   Drug concentration in bottle: 50 mg/ml *Store at 4˚ C
   How to use: Drug is viscous and needs to be diluted in sterile water 1:10 or more.  
   Administer injectable solution as below using a 25 or 27g needle.  The carprofen 
   chewable tablet may be used to extend analgesic coverage beyond 24 hours after the 
   initial carprofen injection.
   Dosages:
   Rats: 5-10 mg/kg SC every 24 hours for up to 3 days
   Mice: 5-10 mg/kg SC every 12 hours for up to 3 days

D. Meloxicam (Metacam®)  Non-steroidal anti-inflammatory (NSAID)

1. Meloxicam Oral (chewable tab): available from Bio-Serv
   Flavored, nutritionally complete chewable 5 gram tablet
   How to use: Placebo tab (no meloxicam) can be used 3 days prior to surgery to acclimate 
   the animal. Place on the cage floor for easy access. 
   Dosages:
   Rats: One 5 gm tablet/rat/day (0.5 mg meloxicam/tablet)
   Mice: One 5 gm tablet/mouse/day (0.125 mg meloxicam/tablet)

2. Meloxicam Injectable*: (5 mg/ml)
   How to use: Administer injectable solution as below using a 25 or 27g needle. 
   Dosages:
   Rats: 1 mg/kg SC every 12-24 hours for up to 3 days
   Mice: 5-10 mg/kg every 8-12 hours for up to 3 days

   [Meloxicam-SR is not recommended for use in rodents]

3. Meloxicam Oral Solution (for oral dosing): (1.5 mg/ml)
   How to use: Drug must be diluted with sterile diluent 1:10 prior to use. Specific training in 
   oral dosing by gavage is required. Contact DCM to arrange training.
   Dosages:
   Rats: 0.5 mg/kg PO every 12 hours up to 3 days
   Mice: 2.5 - 5 mg/kg PO every 12 hours up to 3 days
II. Local anesthetics that provide analgesia

General considerations for local analgesics:
- Provides local pain relief, and is most effective when injected BEFORE making the incision.
- Use in the skin around the planned incision site for surgeries. Intradermal injection is preferred.
- For thoracotomies, inject into the intercostal space (rib muscles) at the planned site of incision. Can be used to supplement systemic analgesia (opioids, NSAIDS)

A. Bupivacaine (Marcaine®) 0.5%
   Concentration: 5 mg/ml (0.5%); sold in a 50ml vial
   Analgesic duration: 4 – 8 hours, slow onset
   How to use: Dilute in sterile water to 2.5mg/ml (0.25%).
   Dose: Do not exceed 8mg/kg SC

B. Lidocaine (Xylocaine®) 2%
   Concentration: 20 mg/ml (2%); sold in a 50 ml vial
   Analgesic duration: 1 hour, fast onset
   How to use: Some formulations of lidocaine include epinephrine to promote vasoconstriction (to keep anesthetic agent in area longer). Do not use if epinephrine will complicate research study. Dilute with sterile water to final concentration of 5 mg/ml (0.5%) before use.
   Dose: Do not exceed 7 mg/kg

III. Documentation of Analgesic Administration

Administration of post-operative analgesics must be documented. Federal regulators and inspectors consider a lack of documentation to mean analgesics were not provided and would classify that event as non-compliance. Please use the links below for more information about how to document analgesic administration.

Post-Surgical Monitoring Records (Green Cards) are required for all survival surgery procedures. They may also be required for prolonged anesthesia exposure or other painful procedures as described in your approved IACUC protocol.
